## Least Squares Derivation

Bookmark this page

#### DEFINITION: TRANSPOSE OF A MATRIX

Given the following 3×2 matrix

$$X = \begin{pmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \\ \dots & \dots \end{pmatrix}$$

The transpose of the above matrix is of the form:

$$X^T = \begin{pmatrix} x_{11} & x_{21} & \dots \\ x_{12} & x_{22} & \dots \end{pmatrix}$$

In transpose, rows become columns and columns become rows.

You can perform transpose over numpy objects by calling

or

.

#### DEFINITION: INVERSE OF A MATRIX

When we multiply a number by its reciprocal, we get 1.

For a number  $n$ ,

$$n \cdot \frac{1}{n} = 1$$

Similarly, when we multiply a matrix by its inverse, we get the Identity matrix.

For a matrix  $A$ ,

$$A A^{-1} = I$$

is used to calculate the inverse of a matrix, if it exists.

## Multiple Linear Regression

In Multiple Linear Regression, the model takes a simple algebraic form:

$$Y = X \beta$$

We will again choose the MSE as our loss function, which can be expressed in vector notation as:

$$MSE(\beta) = \frac{1}{n} \|Y - X \beta\|^2$$

$$MSE(\beta) = \frac{1}{n} \sum_{i=1}^n (y_i - x_{i1}\beta_1 - x_{i2}\beta_2)^2$$

Taking the derivative of the loss i.e. MSE with respect to the model parameter  $\beta$  gives:

$$\frac{\partial L}{\partial \beta} = -2X^T(Y - X\beta)$$

For optimization, we set the values of the partial derivative to zero, i.e.

$$\begin{aligned}\frac{\partial L}{\partial \beta} = 0 &\Rightarrow -2X^T(Y - X\beta) = 0 \\ &\Rightarrow X^T(Y - X\beta) = 0\end{aligned}$$

Optimization of the previous equation gives:

$$X^T X \beta = X^T Y$$

Multiplying both sides with  $(X^T X)^{-1}$ , we get:

$$(X^T X)^{-1} X^T X \beta = (X^T X)^{-1} X^T Y$$

Thus, we get

$$\beta = (X^T X)^{-1} X^T Y$$

Backtracking this equation to fit the model optimization problem, we have

$$\hat{\beta} = (X^T X)^{-1} X^T Y = \underset{\beta}{\operatorname{argmin}} MSE(\beta)$$
